Abstract

DoCarmo-Wallach theory and its subsequent refinements assert the rich abundance of spherical minimal immersions, minimal immersions of round spheres into round spheres. A spherical minimal immersion is a conformal minimal immersion \( f : \mathbb{S}^m \to \mathbb{S}^n \); its components are spherical harmonics of a common order \( p \) on \( \mathbb{S}^m \), and the conformality constant is \( \lambda_p/m \), where \( \lambda_p \) is the \( p \)th eigenvalue of the Laplace operator on \( \mathbb{S}^m \). In this paper we impose the

¹This work was carried out during the sabbatical leave of the first author at Rutgers University, Camden, New Jersey, USA.
additional constraint of “isotropy” expressed in terms of the higher fundamental forms of such immersions, and determine the dimension of the respective moduli space. By the work of Tsukada, isotropy can be characterized geometrically by “helicality,” constancy of initial sequences of curvatures of the image curves of geodesics under the respective spherical minimal immersions. We first give a simple criterion for (the lowest order) isotropy of a spherical minimal immersion in terms of orthogonality relations in the third (ordinary) derivative of the image curves (Theorem A). This is then applied in the main result of this paper (Theorem B) which gives a full characterization of isotropic SU(2)-equivariant spherical minimal immersions of $S^3$ into the unit sphere of real and complex SU(2)-modules. Specific examples include the polyhedral minimal immersions of which the icosahedral minimal immersion (into $S^{12}$) is isotropic whereas its tetrahedral and octahedral cousins are not.

1 Introduction

Minimal isometric immersions of round spheres into round spheres form a rich and subtle class of objects in differential geometry studied by many authors; see [1, 4, 5, 6, 7, 8, 10, 12, 15, 16, 17, 18, 19, 20, 26, 27, 28, 29]; and, for a more complete list, the bibliography at the end of the second author’s monograph [22]. Such immersions can be written as $f : S^m \rightarrow S_V$ of the round $m$-sphere $S^m_\kappa$ of (constant) curvature $\kappa > 0$ into the unit sphere $S_V$ of a Euclidean vector space $V$; or, scaling the domain sphere $S^m_\kappa$ to radius one, as minimal immersions $f : S^m \rightarrow S_V$ with homothety constant $1/\kappa$. By minimality, the components $\alpha \circ f$, $\alpha \in V^*$ (the dual of $V$), of $f$ are necessarily eigenfunctions of the Laplacian $\Delta$ of $S^m$ corresponding to the eigenvalue $\lambda = m/\kappa$. Setting $\lambda = \lambda_p = p(p + m - 1)$, $p \geq 1$, the $p$th eigenvalue, and $\mathcal{H}_m^p \subset C^\infty(S^m)$, the corresponding eigenspace of spherical harmonics of order $p$ on $S^m$, a homothetic minimal immersion $f : S^m \rightarrow S_V$ with homothety constant $\lambda_p/m$ is called a spherical minimal immersion of degree $p$. (For the standard results recalled here and below, see [22, Appendix 2], or [28] as well as the summary in [27].)

Beyond the classical Veronese immersions $\text{Ver}_p : S^2 \rightarrow S^{2p}$, $p \geq 2$, and various generalizations, it is well-known that spherical minimal immersions abound. (For many specific examples, see [5, 6, 27].)

According to the DoCarmo-Wallach theory, for $m \geq 3$ and $p \geq 4$, the set of spherical minimal immersions $f : S^m \rightarrow S_V$ of degree $p$ can be parametrized by a (non-trivial) compact convex body $\mathcal{M}_m^p$ in a linear subspace $\mathcal{F}_m^p$ of the symmetric square $S^2(\mathcal{H}_m^p)$. More precisely, this is a parametrization of the congruence classes of full spherical minimal immersions, where a spherical minimal immersion $f : S^m \rightarrow S_V$ is
full if the image of $f$ spans $V$, and two full spherical minimal immersions $f : S^m \to S_V$ and $f' : S^m \to S_{V'}$ are congruent if $f' = U \circ f$ for some linear isometry $U : V \to V'$. The convex body $M_f$ is called the moduli space for spherical minimal immersions $f : S^m \to S_V$ of degree $p$. (The moduli space $M_f$ is trivial (zero-dimensional singleton) if and only if $m = 2$ (and $p \geq 1$) or $p \leq 3$ (and $m \geq 2$). For the original work of DoCarmo and Wallach, see [7] as well as [28].)

The group $SO(m+1)$ acts on the set of all spherical minimal immersions by pre-composition, and this action naturally carries over to the moduli space $M_f$. This latter action, in turn, is the restriction of the $SO(m+1)$-module structure on $S^2(H^p_m)$ (extended from that of $H^p_m$) with $F^p_m$ being an $SO(m+1)$-submodule. The complexification of $F^p_m$ decomposes as

$$F^p_m \otimes \mathbb{C} \cong \sum_{(u,v) \in \Delta^p_2, \, u,v \text{ even}} V_{m+1}^{(u,v,0,\ldots,0)},$$

where $\Delta^p_2 \subset \mathbb{R}^2$ is the closed convex triangle with vertices $(4,4)$, $(p,p)$, $(2p - 4, 4)$. Here $V_{m+1}^{(u_1,\ldots,u_d)}$ denotes the complex irreducible $SO(m+1)$-module with highest weight vector $(u_1,\ldots,u_d)$ relative to the standard maximal torus in $SO(m+1)$. Since the dimension of the irreducible components in (1) can be explicitly calculated by the Weyl-dimension formula, we obtain the exact dimension

$$\dim M_f = \dim F^p_m$$

of the moduli space. (The fact that the right-hand side in (1) is a lower bound for $F^p_m \otimes \mathbb{R} \subset \mathbb{C}$ is the main result of the DoCarmo-Wallach theory. The equality, the so-called exact dimension conjecture of DoCarmo-Wallach, was proved by the second author in [25]; see also [22, Chapter 3], and also a subsequent different proof in [29].)

The dimension as well as the subtlety of the moduli space $M_f$ increase rapidly with $m \geq 3$ and $p \geq 4$. It is therefore natural to impose further geometric restrictions on the spherical minimal immersions. These, on the one hand, reduce the dimension and complexity of the moduli space, and, on the other hand, give new examples of spherical minimal immersions with additional properties. As we will see below, two competing natural geometric properties of spherical minimal immersions are “isotropy” and “helicality.”

Let $f : S^m \to S_V$ be a spherical minimal immersion of degree $p$. For $k = 1, \ldots, p$, let $\beta_k(f)$ be the $k$th fundamental form of $f$, and $O^k_f$ the $k$th osculating bundle of $f$, both defined on a (maximal) open and dense subset $D_f \subset S^m$. (For a summary on higher fundamental forms, see [28] or [10], and also Section 2.1 below.)

**Definition of Isotropy:** Let $k \geq 2$. A spherical minimal immersion $f : S^m \to S_V$ is said to be isotropic of order $k$ if $\|\beta_l(f)(X,X,\ldots,X)\|$ are universal constants $\Lambda_l$, $2 \leq l \leq k$, (depending only on $m$ and $p$) for all unit vectors $X \in T_x(S^m)$, $x \in D_f$. The constants $\Lambda_l$, $l \geq 2$, are called the constants of isotropy. Since the first fundamental
form of $f$ is the differential $f_*$, it is convenient to set $\Lambda_1 = \sqrt{\lambda_p/m}$ with $\Lambda_2 = \lambda_p/m$ being the homothety constant. (For an extensive study of isotropy, see Tsukada’s work [26].)

The moduli space $\mathcal{M}^{p,k}_m$ parametrizing the spherical minimal immersions $f : S^m \to S^V$ of degree $p$ that are isotropic of order $k$ is a linear slice of the moduli space $\mathcal{M}^p_m$ by an $SO(m+1)$-submodule $\mathcal{F}^{p,k}_m \subset \mathcal{F}^p_m$. We have the decomposition

$$\mathcal{F}^{p,k}_m \otimes \mathbb{C} \cong \sum_{(u,v) \in \Delta_{k+1}} V^p_{m+1},$$

where the closed convex triangle $\Delta^p_k \subset \mathbb{R}^2$, $k = 2, 3, \ldots, [p/2]$, has vertices $(2k, 2k)$, $(p, p)$, and $(2(p-k), 2k)$. As before, (2) gives the exact dimension of the moduli space: $\dim \mathcal{M}^{p,k}_m = \dim \mathcal{F}^{p,k}_m$. (These results have been proved by Gauchman and the second author, for $m \geq 4$, in [10]; and the case $m = 3$ has been completed in [22].)

We thus have the filtration

$$\mathcal{F}^p_m = \mathcal{F}^{p,1}_m \supset \mathcal{F}^{p,2}_m \supset \cdots \supset \mathcal{F}^{p,[p/2]-1}_m,$$

where each term is obtained from the decomposition above by restriction to the respective triangle in the sequence

$$\Delta^p_2 \supset \Delta^p_3 \supset \cdots \supset \Delta^p_{[p/2]}.$$ As a byproduct, we obtain that for $p \leq 2k + 1$ the moduli space $\mathcal{M}^{p,k}_m$ is trivial. (For the original proof of this, see again [26].)

A geometric characterization of isotropy lies in the concept of “helicality” introduced and studied by Sakamoto in a series of papers [17, 18, 19].

**Definition of Helicality:** A spherical minimal immersion $f : S^m \to S^V$ of degree $p$ is called helical up to order $k$ if, for any arc-length parametrized geodesic $\gamma : \mathbb{R} \to S^m$, the first $k-1$ curvatures of the image curve $\sigma = f \circ \gamma : \mathbb{R} \to S^V$ are non-zero constants, and these constants are universal in that they do not depend on the choice of $\gamma$ but only on $m$ and $p$.

(Recall that the curvatures are obtained by taking higher order covariant derivatives of $\sigma'$. Note also that the universal constants have been determined in [9].)

Tsukada’s characterization of isotropy (with appropriate modifications of his proof of Proposition 5.1 in [26]) is the following:

**Theorem** A spherical minimal immersion $f : S^m \to S^V$ of degree $p$ is isotropic of order $k$ if and only if it is helical up to order $k$. 

4
The applications of this result are severalfold. First, a geometrically transparent interpretation of the moduli space $\mathcal{M}_{m}^{p,k}$ emerges: it parametrizes the spherical minimal immersions $f : S^{m} \to S_{V}$ of degree $p$ that are helical up to order $k$. Second, as noted above, $\dim \mathcal{M}_{m}^{p,k}$ can be calculated explicitly. In the past helical minimal immersions have only been studied individually, and here we have a precise formula for the dimension of the moduli space of such maps. Third, helicality is a much simpler condition than isotropy, therefore, in several instances, this condition can be checked by explicit calculation. (See the examples in Section 2.4 and the computations in Section 3.2 below.)

The complexity of the condition of isotropy/helicality increases rapidly with the order. The lowest order of isotropy, isotropy of order two, has special significance because of the relative simplicity of the formula expressing the first curvature of the image curve of a geodesic under the immersion. Our first result is the following:

**Theorem A** Let $f : S^{m} \to S_{V}$ be a spherical minimal immersion of degree $p$. For a unit vector $X \in T_{x}(S^{m})$, let $\gamma_{X} : \mathbb{R} \to S^{m}$ be the (arc-length parametrized) geodesic such that $\gamma_{X}(0) = x$ and $\gamma'_{X}(0) = X$, and set $\sigma_{X} = f \circ \gamma_{X} : \mathbb{R} \to S_{V}$. Then $f : S^{m} \to S_{V}$ is isotropic of order two if and only if, for any $x \in S^{m}$, and $X,Y \in T_{x}(S^{m})$ with $\langle X,Y \rangle = 0$, we have

$$\langle \sigma_{X}^{(3)}(0), \sigma'_{Y}(0) \rangle = 0.$$  \hspace{1cm} (3)

Here $\sigma_{X}^{(k)}$, $k \geq 1$, is the $k$th derivative of $\sigma_{X}$ as a vector-valued function (with values in $V$) and viewed as a vector field along the curve $\sigma_{X}$. If $f : S^{m} \to S_{V}$ is an isotropic spherical minimal immersion of degree $p$ then, for the isotropy constant $\Lambda_{2}$, we have

$$\langle \sigma_{X}^{(3)}(0), \sigma'_{X}(0) \rangle = -\Lambda_{2}^{2}, \quad \|X\| = 1, \quad X \in T_{x}(S^{m}), \quad x \in S^{m},$$  \hspace{1cm} (4)

where $\Lambda_{2}^{2} = \lambda_{p}/m$.

As shown by the works of DeTurck and Ziller [5, 6], a rich subclass of spherical minimal immersions is comprised by minimal $SU(2)$-orbits in spheres (of $SU(2)$-modules). Let $W_{p}$, $p \geq 0$, be the space of complex homogeneous polynomials of degree $p$ in two variables $z,w \in \mathbb{C}$. Then $W_{p}$ is a complex irreducible $SU(2)$-module. Given a (nonzero) polynomial

$$\xi = \sum_{q=0}^{p} c_{q}z^{p-q}w^{q} \in W_{p},$$  \hspace{1cm} (5)

we consider the orbit map $f_{\xi} : S^{3} \to W_{p}$, $f_{\xi}(g) = g \cdot \xi = \xi \circ g^{-1}$, $g \in SU(2)$, through $\xi$. (This so-called equivariant construction has been initiated by K. Mashimo [12].)
Now $f_\xi$ maps into a unit sphere $S_{W_p}$ if and only if

$$\|\xi\|^2 = \sum_{q=0}^{p}(p-q)!q!|c_q|^2 = 1. \quad (6)$$

Assuming this, we obtain an $SU(2)$-equivariant map $f_\xi : S^3 \rightarrow S_{W_p}$.

DeTurck and Ziller showed that $f_\xi$ is a spherical minimal immersion of degree $p$, that is, $f_\xi$ is homothetic with homothety constant $\Lambda_1^2 = \lambda_0/3 = p(p+2)/3$, if and only if

$$p\sum_{q=0}^{p}(p-q)!q!|c_q|^2 = 1.$$ 

(For more details, see [5, 6] or [27, 22].)

Our main result gives a full characterization of order two isotropic $SU(2)$-equivariant spherical minimal immersions $f : S^3 \rightarrow S_{W_p}$ of degree $p$ as follows:

**Theorem B** Let $f : S^3 \rightarrow S_{W_p}$ be an $SU(2)$-equivariant spherical minimal immersion of degree $p$. Setting $f = f_\xi$ with $\xi \in W_p$ satisfying (5)-(9), $f_\xi$ is isotropic of order two if and only if the following system of equations holds

$$\sum_{q=0}^{p-2}(p-q)!(q+2)!c_q\bar{c}_{q+2} = 0,$$ 

$$\sum_{q=0}^{p-1}(p-q)!(q+1)!(p-2q-1)c_q\bar{c}_{q+1} = 0,$$ 

$$\sum_{q=0}^{p}(p-q)!q!(p-2q)^2|c_q|^2 = \Lambda_1^2.$$ 

(10) 

(11) 

(12) 

(13) 

(14)
where, for the second constant of isotropy $\Lambda_2$, we have

$$\Lambda_2^2 = \frac{p(p + 2)(p(p + 2) - 3)}{5}. \quad (15)$$

To exhibit specific examples of isotropic $SU(2)$-equivariant spherical minimal immersions $f_\xi : S^3 \to S_{W_p}$ thus amounts to solve the system of equations (6)-(15). We will do this in Section 2.4.

The systems (7)-(9) and (10)-(14) are special cases of a general pattern, and it is reasonable to pose the following:

**Main Conjecture** Let $f_\xi : S^3 \to S_{W_p}$, $\xi \in W_p$, be an $SU(2)$-equivariant spherical minimal immersion of degree $p$ and order of isotropy $k - 1$. Then $f_\xi$ is isotropic of order $k$ if and only if we have

$$
\sum_{q=0}^{p-l} (p - q)!(q + l)! (p - 2q - l)^{2k-l} c_q e_{q+l} = \delta_{0l}(\Lambda_1^2 + \ldots + \Lambda_k^2), \quad l = 0, 1, \ldots, 2k, \quad (16)
$$

where $\Lambda_1, \ldots, \Lambda_k$ are the first $k$ constants of isotropy, and $\delta$ is the Kronecker delta.

As noted above, for $k = 1$ and $k = 2$, (16) specializes to (7)-(9) and (10)-(14), respectively. (For easier reference, in these special cases, we preferred to give the expanded systems above.)

## 2 Preliminaries

### 2.1 Higher Fundamental Forms and Isotropy

Let $f : S^m \to S_V$ be a spherical minimal immersion of degree $p$. For $k = 1, \ldots, p$, we define $\beta_k(f)$, the $k$th fundamental form of $f$, and $O^k_f$, the $k$th osculating bundle of $f$. For $k = 1$, we set $\beta_1(f) = f_*$, the differential of $f$, and $O^1_f = T(S^m)$ regarded as a subbundle of the pull-back $f^*T(S_V)$. For $k \geq 2$, the $k$th osculating bundle $O^k_f$ is a subbundle of the normal bundle $N_f$ of $f$. The higher fundamental forms and osculating bundles are defined on a (maximal) open dense set $D_f \subset S^m$. On $D_f$, the $k$th fundamental form is a bundle map $\beta_k(f) : S^k(T(S^m)) \to O^k_f$, which is fibrewise
onto. The higher fundamental forms are defined inductively as
\[
\beta_k(f)(X_1, \ldots, X_k) = (\nabla^k X \beta_{k-1}(f))(X_1, \ldots, X_{k-1})^1_{k-1},
\]
where \(\nabla^k\) is the natural connection on the normal bundle \(N_f\), and \(\perp_{k-1}\) is the orthogonal projection with kernel \(O^k_{f,ix} \oplus O^k_{j,ix} \oplus \cdots \oplus O^k_{f,ix}\) (\(O^0_{f,ix} = \mathbb{R} \cdot f(x)\)), and \(D^k_f\) is the set of points \(x \in D^k_f\) at which the image \(O^k_{f,ix}\) of \(\beta_k(f)\) has maximal dimension. We set \(D_f = \bigcap_{k=0}^p D^k_f\).

In the definition of isotropy of the previous section the higher fundamental forms have identical (vectorial) arguments. It is desirable and more revealing to have an equivalent formulation of isotropy with independent vectorial arguments. (This has been used by Tsukada in [26] as well as by Gauchman and the second author in [10].)

First, we define the Dirac delta \(\delta_{m,p} : S^m \to S^{(\mathcal{H}^p_m)}\), by evaluating spherical harmonics in \(\mathcal{H}^p_m\) on points of \(S^m\) [29]. (The Dirac delta is also known as the standard minimal immersion; see [7, 28].) Then \(\delta_{m,p}\) is \(SO(m+1)\)-equivariant with respect to the \(SO(m+1)\)-module structure of \((\mathcal{H}^p_m)^* \cong \mathcal{H}^p_m\). We write \(S^m = SO(m+1)/SO(m)\) with isotropy subgroup \(SO(m+1)_o = SO(m) \oplus [1] \cong SO(m)\) at the base point \(o = (0, \ldots, 0, 1)\). Since \(SO(m)\) acts irreducibly on \(T_o(S^m)\), the Dirac delta \(\delta_{m,p}\) is homothetic, and therefore a spherical minimal immersion. Moreover, branching (from \(SO(m+1)\) to \(SO(m)\)) gives
\[
\mathcal{H}^p_m|_{SO(m)} = \mathcal{H}^0_{m-1} \oplus \mathcal{H}^1_{m-1} \oplus \cdots \oplus \mathcal{H}^p_{m-1},
\]
and this corresponds to the decomposition of the osculating spaces
\[
O^0_{\delta_{m,p},o} \oplus O^1_{\delta_{m,p},o} \oplus \cdots \oplus O^p_{\delta_{m,p},o}.
\]
(See again [7, 28].)

In a technical argument [26, Proposition 3.1] Tsukada gave the following equivalent formulation of isotropy:
A spherical minimal immersion \(f : S^m \to S^r\) is isotropic of order \(k\), \(2 \leq k \leq p\), if and only if, for \(2 \leq l \leq k\), we have
\[
\langle \beta_l(f)(X_1, \ldots, X_l), \beta_l(f)(X_{l+1}, \ldots, X_{2l}) \rangle
= \langle \beta_l(\delta_{m,p})(X_1, \ldots, X_l), \beta_l(\delta_{m,p})(X_{l+1}, \ldots, X_{2l}) \rangle,
\]
\[
X_1, \ldots, X_{2l} \in T_x(S^m), \ x \in D_f.
\]
(Note that, for \(X = X_1 = \ldots = X_{2l}\) (and of unit length) this specializes to the definition of isotropy we gave in Section 1.)
The condition of isotropy (18) implies that, for \(2 \leq l \leq k\), the osculating bundles \(O^l_f\)
of $f$ are isomorphic with those of the Dirac delta $\delta_{m,p}$. In view of the decomposition of the osculating spaces for $\delta_{m,p}$ above, for a spherical minimal immersion $f : S^m \to S_V$ that is isotropic of order $k$, we have the lower bound

$$\dim V \geq \dim(\mathcal{H}_m^0 \oplus \mathcal{H}_m^1 \oplus \ldots \oplus \mathcal{H}_m^k) = \dim \mathcal{H}_m^k.$$  \hfill (19)

### 2.2 The Lowest Order Isotropy

In this short section we obtain a simple condition for isotropy of order two of a spherical minimal immersion. This will be used to prove Theorem A in Section 3.1.

For brevity, we will suppress the order, and refer to a spherical minimal immersion of degree $p$ and order of isotropy two simply as an isotropic spherical minimal immersion (of degree $p$).

**Remark** The moduli space parametrizing the (congruence classes of full) isotropic spherical minimal immersions is $\mathcal{M}_m^{p,2}$ which, by (2), is non-trivial if and only if $p \geq 6$.

By definition, a spherical minimal immersion $f : S^m \to S_V$ is isotropic (of order two) if $\|\beta(f)(X,X)\|$ is a universal constant $\Lambda_2$ for all unit vectors $X \in T_x(S^m)$, $x \in S^m$.

It is well-known that this holds if (and only if) the second fundamental form $\beta(f)$ is pointwise isotropic, that is, for any $x \in S^m$, $\beta(f)$ is isotropic on the tangent space $T_x(S^m)$ as a symmetric bilinear form in the classical sense (with $\|\beta(f)(X,X)\|$ being independent of the unit vector $X \in T_x(S^m)$). (See for example [26, Proposition 3.1].) Isotropy (at a point) can be conveniently reformulated in terms of the shape operator $\mathcal{A}(f)$ of $f : S^m \to S_V$ as

$$\mathcal{A}(f)_{\beta(f)(X,X)} X \wedge X = 0, \quad X \in T_x(S^m), \quad x \in S^m. \hfill (20)$$

Indeed, for $x \in S^m$, polarizing $\|\beta(f)(X,X)\|^2$, $X \in T_x(S^m)$, we see that $\beta(f)$ is isotropic on $T_x(S^m)$ if and only if

$$\langle \beta(f)(X,X), \beta(f)(X,Y) \rangle = \langle \mathcal{A}_{\beta(f)(X,X)} X, Y \rangle = 0$$

for all $X,Y \in T_x(S^m)$ with $\langle X,Y \rangle = 0$. (See also [18, (2.2)] or [4, Section 2].)

As expected, higher order isotropy is more complex. For completeness, we briefly indicate the condition analogous to (20). Let $X \in T_x(S^m)$, $x \in D_f$, and denote by $\zeta_k$ a (locally defined) section of the osculating bundle $\mathcal{O}_f^k$. (We use the notations in the previous section, and tacitly assume that we work over $D_f \subset S^m$ so that all
osculating bundles are well-defined.) We define $T^k$ by
\[ T^k_X(\zeta_{k-1}) = (\nabla^\perp_X \zeta_{k-1})^{O^k}, \]
where $\nabla^\perp$ is the connection of the normal bundle $N_f$ and the osculating bundle in the superscript indicates orthogonal projection. By (17), we have
\[ \beta_k(f)(X_1, \ldots, X_k) = T^k_X(\beta_{k-1}(f)(X_2, \ldots, X_k)) \]
for (locally defined) vector fields $X_1, \ldots, X_k$ on $D_f$.

Let $S_{X}^{k-1}$ be the adjoint of $T^k_X$ (with respect to the bundle metrics on the respective osculating bundles induced by the Riemannian metric on $S^m$). Clearly, we have
\[ S_{X}^{k-1}(\zeta_k) = - (\nabla^\perp_X \zeta_k)^{O^{k-1}}. \]

Now, polarizing $\|\beta_k(f)(X, \ldots, X)\|^2$ as before, we obtain that, for $x \in S^m$, $\beta_k(f)$ is isotropic on $T_x(S^m)$ if and only if
\[ \langle \beta_k(f)(X, \ldots, X), \beta_k(f)(X, \ldots, X, Y) \rangle = 0 \]
whenever $X, Y \in T_x(S^m)$ with $\langle X, Y \rangle = 0$. We now calculate
\[
\langle \beta_k(f)(X, \ldots, X), \beta_k(f)(X, \ldots, X, Y) \rangle \\
= \langle \beta_k(f)(X, \ldots, X), T^k_X(\beta_{k-1}(f)(X_2, \ldots, X_k)) \rangle \\
= \langle S_{X}^{k-1} \beta_k(f)(X_2, \ldots, X), \beta_{k-1}(f)(X_2, \ldots, X, Y) \rangle \\
= \langle S_{X}^2 S_{X}^3 \cdots S_{X}^{k-1} \beta_k(f)(X, \ldots, X), \beta(f)(X, Y) \rangle \\
= \langle A(f) s_{X}^2 s_{X}^3 \cdots s_{X}^{k-1} \beta_k(f)(X, \ldots, X), X, Y \rangle.
\]

Summarizing, we obtain that, for $x \in S^m$, $\beta_k(f)$, $k \geq 3$, is isotropic on $T_x(S^m)$ if and only if, we have
\[ A(f) s_{X}^2 s_{X}^3 \cdots s_{X}^{k-1} \beta_k(f)(X, \ldots, X) X \wedge X = 0, \quad X \in T_x(S^m). \]

**Remark** Another approach for order $k$ isotropy in general is derived by Hong and Houh in [11, Theorem 2.3]. The first $k - 1$ curvatures are constant if and only if, for $2 \leq l \leq 2k - 1$, we have
\[ A(f)_{(D^l-2\beta(f))(X, \ldots, X)} X \wedge X = 0, \quad X \in T_x(S^m), \quad x \in S^m, \]
where $D$ is the covariant differentiation on $T(M) \oplus N_f$ with $N_f$ being the normal bundle of $f$. (Note that, in this case, $A(f)_{(D^l-2\beta(f))(X, \ldots, X)} X = 0$ for $l$ odd.)

These conditions are formulated in terms of the notion of contact number of Euclidean submanifolds. See [2, 3] for details for pseudo-Euclidean submanifolds. The first author generalized this notion for the case of affine immersions in projectively flat space; see [14].
As noted in Section 1 the moduli space $M^p_m$ parametrizing the congruence classes of full spherical minimal immersions $f : S^m \rightarrow S^V$ of degree $p$ is non-trivial if and only if $m \geq 3$ and $p \geq 4$. The lowest dimension of the domain $S^m$ for non-trivial moduli is $m = 3$. This case is of special interest since the product $SU(2) \times SU(2)$ double covers the acting isometry group $SO(4)$. The (projection of the) first factor $SU(2)$ in this product is an isomorphic copy of $SU(2)$, and it can be realized as a subgroup of $SO(4)$ by identifying $\mathbb{R}^4$ and $\mathbb{C}^2$ in the usual way: $\mathbb{R}^4 \ni (x, y, u, v) \mapsto (z, w) = (x + iy, u + iv) \in \mathbb{C}^2$. With this identification

$$SU(2) = \left\{ \begin{bmatrix} a & -\bar{b} \\ b & \bar{a} \end{bmatrix} \right\} \mid |a|^2 + |b|^2 = 1, \; a, b \in \mathbb{C} \right\}$$

becomes a subgroup of $SO(4)$. (Note that this also shows that $SU(2) = S^3$, where the latter is the unit sphere in $\mathbb{C}^2$.)

The orthogonal matrix $\gamma = \text{diag} (1, 1, 1, -1) \in O(4)$ (or, in complex coordinates, $\gamma : z \mapsto z, w \mapsto \bar{w}, (z, w) \in \mathbb{C}^2$) conjugates $SU(2)$ to the subgroup $SU(2)' = \gamma SU(2) \gamma \subset SO(4), \; \gamma^{-1} = \gamma$.

This is the projection of the second factor in the product $SU(2) \times SU(2)$ to $SO(4)$ via the double cover. Both subgroups $SU(2)$ and $SU(2)'$ are normal in $SO(4)$ and we have $SU(2) \cap SU(2)' = \{ \pm I \}$.

In view of this it is natural to consider (full) spherical minimal immersions $f : S^3 \rightarrow S^V$ of degree $p$ that are $SU(2)$-equivariant, that is, there exists a homomorphism $\rho_f : SU(2) \rightarrow SO(V)$ such that

$$f \circ g = \rho_f(g) \circ f, \; g \in S^3.$$ 

The homomorphism $\rho_f$ (associated to $SU(2)$-equivariance) defines an $SU(2)$-module structure on the Euclidean vector space $V$. Moreover, the natural isomorphism between $V$ and the space of components $V_f = \{ \alpha \circ f \mid \alpha \in V^* \} \subset H^p_3$ (through the dual $V^*$) is $SU(2)$-equivariant, and we obtain that $V$ is an $SU(2)$-submodule of the restriction $H^p_3|_{SU(2)}$.

In general, the irreducible complex $SU(2)$-modules are parametrized by their dimension, and they can be realized as submodules appearing in the (multiplicity one) decomposition of the $SU(2)$-module of complex homogeneous polynomials $\mathbb{C}[z, w]$ in two variables. For $p \geq 0$, the $p$th submodule $W_p$, $\dim_\mathbb{C} W_p = p + 1$, comprises the homogeneous polynomials of degree $p$. With respect to the $L^2$-scalar product (suitably scaled) the standard orthonormal basis for $W_p$ is $\{ z^{p-q} w^q / \sqrt{(p-q)!q!} \}_{q=0}^p$. For
\( p \) odd, \( W \) is irreducible as a real \( SU(2) \)-module. For \( p \) even, the fixed point set \( R \) of the complex anti-linear self map \( z^q w^{p-q} \mapsto (-1)^q z^p w^q \), \( q = 0, \ldots, p \), of \( W \) is an irreducible real submodule with \( W = R \otimes \mathbb{R} \). For the space of complex-valued spherical harmonics \( H^p \) of order \( p \), we have

\[
H^p = W_p \otimes W'_p,
\]
as complex \( SO(4) \)-modules, where \( W'_p \) is the \( SU(2)' \)-module obtained from the \( SU(2) \)-module \( W_p \) via conjugation by \( \gamma \), and the tensor product is understood by the double cover \( SU(2) \times SU(2) \to SO(4) \). Restricting to \( SU(2) \), we obtain

\[
H^p = (p + 1)W_p.
\]
as complex \( SU(2) \)-modules.

For real-valued spherical harmonics, for \( p \) even, this gives

\[
H^p = (p + 1)R_p.
\]

Similarly, for \( p \) odd, we have

\[
H^p = \frac{p + 1}{2} W_p
\]
as real \( SU(2) \)-modules.

Returning to our \( SU(2) \)-equivariant spherical minimal immersion \( f : S^3 \to S_V \), we see that the \( SU(2) \)-module \( V \) is isomorphic with a multiple of \( R \) for \( p \) even, and a multiple of \( W_p \) for \( p \) odd. As a byproduct, we also obtain that the dimension of \( V \) is divisible by \( p + 1 \) if \( p \) is even, and by \( 2(p + 1) \) if \( p \) is odd.

**Remark** \( SU(2) \)-equivariant spherical minimal immersions \( f : S^3 \to S_V \) of degree \( p \) that are isotropic of order \( k \) are parametrized by the \( SU(2) \)-equivariant moduli space \( (\mathcal{M}^{p,k})^{SU(2)} \). It is a compact convex body in the fixed point set \( (\mathcal{F}^{p,k})^{SU(2)} \) which, in view of the double cover \( SU(2) \times SU(2) \to SO(4) \), is an \( SU(2)' \)-module. We have

\[
(\mathcal{F}^{p,k})^{SU(2)} = \sum_{q=k+1}^{[p/2]} R'_{4q},
\]
as real \( SU(2)' \)-modules. In particular, we have the dimension formula

\[
\dim(\mathcal{M}^{p,k})^{SU(2)} = \dim(\mathcal{F}^{p,k})^{SU(2)} = \left( 2 \left\lfloor \frac{p}{2} \right\rfloor + 2k + 3 \right) \left( \left\lceil \frac{p}{2} \right\rceil - k \right), \quad p \geq 2k + 2. \tag{23}
\]

To seek explicit examples of \( SU(2) \)-equivariant spherical minimal immersions \( f : S^3 \to S_V \), it is natural to consider the simplest case when \( V = W_p \) (regardless the parity of \( p \)).
Examples The quartic \((p = 4)\) minimal immersion \(I : S^3 \to S_{W_4} = S^9\), the \(SU(2)\)-orbit map of the polynomial \(\xi = (\sqrt{6}/24)(z^4 - w^4) + (\sqrt{2}/4)z^2w^2 \in W_4\), is archetypal in understanding the structure of the moduli space \((\mathcal{M}^3_{SU(2)})\) and thereby \(\mathcal{M}^3_{SU(2)}\); see \([27]\). Moreover, the sextic \((p = 6)\) tetrahedral minimal immersion \(Tet : S^3 \to S_{R_6} = S^6\), the \(SU(2)\)-orbit map of the polynomial \(\xi = (1/(4\sqrt{15}))zw(z^4 - w^4) \in R_6 \subset W_6\), is a famous example because it realizes the minimum range dimension among all non-standard spherical minimal immersions of \(S^3\). (For more details, see \([12, 13]\), and for an extensive list of \(SU(2)\)-equivariant spherical minimal immersions, see \([5, 6, 22]\).)

2.4 Isotropic and Non-Isotropic Examples

The archetypal \(SU(2)\)-equivariant spherical minimal immersions are the tetrahedral, octahedral, and icosahedral minimal immersions. As recognized by DeTurck and Ziller in \([5, 6]\), they are the \(SU(2)\)-orbits of Felix Klein’s minimum degree absolute invariants of the tetrahedral, \(T\), octahedral, \(O\), and icosahedral, \(I\), groups in \(R_{2d} \subset W_{2d}\), for \(d = 3, 4, 6\). As such they realize minimal embeddings of the tetrahedral, \(S^3/T^*\), octahedral, \(S^3/O^*\), and icosahedral, \(S^3/I^*\), manifolds, where the asterisk indicates the respective binary groups. (For more details, see also \([22, Section 1.5]\).)

Example 1 The tetrahedral minimal immersion \(Tet : S^3 \to S_{R_6} = S^6\) cannot be isotropic for reasons of dimension since, for any isotropic \(SU(2)\)-equivariant spherical minimal immersion \(f : S^3 \to S_V\), by (19), we have \(\dim V \geq \dim \mathcal{H}_3^2 = 9\).

Example 2 The dimension restriction in the previous example does not exclude the octahedral minimal immersion \(Oct : S^3 \to S_{R_8} = S^8\) to be isotropic; however, it is the \(SU(2)\)-orbit of the octahedral invariant \(\xi = c_0(z^8 + 14z^4w^4 + w^8) \in R_8\), \(c_0 = 1/(96\sqrt{21})\), which does not satisfy (10) or (14). Hence the octahedral minimal immersion is not isotropic.

Example 3 The icosahedral minimal immersion \(I : S^3 \to S_{R_{12}} = S^{12}\) is the \(SU(2)\)-orbit of Klein’s icosahedral invariant \(\xi = c_1(z^{11}w + 11z^6w^6 - zw^{11}) \in R_{12}\), \(c_1 = 1/(3600\sqrt{11})\). It follows by direct substitution that it is isotropic. Note that this has been proved by Escher and Weingart in \([8]\) using basic representation theoretical tools. (See also \([22, Remark 2 in Section 4.5]\).)

Conjecture 1 There are no isotropic spherical minimal immersions \(f : S^3 \to S_{R_8}\) or \(f : S^3 \to S_{R_{10}}\). (Over the reals, (6)-(14) represent 15 quadratic equations, for \(R_8\), in 9 variables, and, for \(R_{10}\), in 11 variables; both highly overdetermined systems.)

Note that if Conjecture 1 holds then the icosahedral minimal immersion is the mini-
Conjecture 2 The icosahedral minimal immersion is unique (up to isometries of the domain and the range) among all isotropic SU(2)-equivariant spherical minimal immersions with range $R_{12}$. (Note that even for $R_{12}$ the system (6)-(14) is slightly overdetermined: 15 equations in 13 variables.)

Example 4 As a slight modification of Example 3 we let $\xi = c_1(z^{11}w + 11iz^6w^6 - zw^{11})$ (with $c_1$ as there). Then $\xi$ belongs to $W_{12}$ (and not $R_{12}$), and the corresponding (full) isotropic SU(2)-equivariant spherical minimal immersion $f_\xi : S^3 \rightarrow S_{W_{12}} = S^{25}$ has the binary dihedral group $D_5^*$ as its invariance group, and it gives a minimal embedding of the dihedral manifold $S^3/D_5^*$ into $S^{25}$.

The isocahedral minimal immersion and this last example are in the complete list of DeTurck and Ziller of all spherical minimal embeddings of 3-dimensional space forms. (See [5, 6] and also [22, Section 1.5].) Using Theorem B, a simple case-by-case check shows that these are the only isotropic spherical minimal immersions in this list.

We have $W_{12} = 2R_{12}$ as real SU(2)-modules, so that Example 4 immediately raises the problem of minimal multiplicity; that is, for given $p \geq 6$ even, what is the minimal $1 \leq k \leq p + 1$ such that an isotropic SU(2)-equivariant spherical minimal immersion $f : S^3 \rightarrow S_{kR_p}$ exists. Using deeper representation theoretical tools, the second author in [23, Corollary to Theorem 3] showed the existence of isotropic SU(2)-equivariant spherical minimal immersions $f : S^3 \rightarrow S_{4R_6}$ and $f : S^3 \rightarrow S_{6R_8}$ (the latter of order of isotropy 3).

Isotropic SU(2)-equivariant spherical minimal immersions with range $W_p$ abound for $p \geq 11$ as the following examples show.

Example 5 Letting $c_q = 0$ for $q \equiv 0 \pmod{5}$, $q = 0, \ldots, 11$, (6)-(14) give

$$|c_0|^2 = \frac{1}{2^9 \cdot 3^3 \cdot 5^4 \cdot 11}, \quad |c_5|^2 = \frac{11}{2^7 \cdot 3^3 \cdot 5^4}, \quad |c_{10}|^2 = \frac{1}{2^9 \cdot 3^3 \cdot 5^4}.$$ Setting $\xi = c_0z^{11} + c_5z^6w^5 + c_{10}zw^{10} \in W_{11}$ we obtain isotropic SU(2)-equivariant spherical minimal immersions $f_\xi : S^3 \rightarrow S_{W_{11}} = S^{23}$.

Example 6 For a somewhat more symmetric example in $W_{12}$, once again letting $c_q = 0$ for $q \equiv 0 \pmod{5}$, $q = 0, \ldots, 12$, by (6)-(14), we have

$$|c_0|^2 = \frac{2^5}{12! \cdot 5^2 \cdot 7}, \quad |c_5|^2 = \frac{2 \cdot 3 \cdot 11}{5! \cdot 7! \cdot 5^2 \cdot 7}, \quad |c_{10}|^2 = \frac{11}{2! \cdot 10! \cdot 5^2}.$$ Setting $\xi = c_0z^{12} + c_5z^7w^5 + c_{10}z^2w^{10} \in W_{12}$, we obtain isotropic SU(2)-equivariant spherical minimal immersions $f_\xi : S^3 \rightarrow S_{W_{12}} = S^{25}$.
3 Proofs

3.1 Proof of Theorem A

We let $\nabla$ denote the Levi-Civita covariant differentiation on $S^m$ and $D$ the covariant (ordinary) differentiation on the Euclidean vector space $V$. Letting $\iota : S_V \to V$ denote the inclusion, we have

$$D_XY = \nabla_XY + \beta(f)(X,Y) - \langle X,Y \rangle \iota,$$  \hfill (24)

for any locally defined vector fields $X,Y$ on $S^m$. As usual, we identify locally defined vector fields with their images under any immersions (such as $f : S^m \to S_V$ and $\iota \circ f : S^m \to V$, etc.). With this, for any unit tangent vector $X \in T_x(S^m)$, $x \in S^m$, we have

$$D_{\sigma'^k} X^{\sigma'}(k) = \sigma'^{(k+1)}(k), \quad k \geq 0,$$  \hfill (25)

as vector fields along $\sigma_X$. Using (24)-(25), we now calculate

$$\sigma''_X = D_{\sigma'_X} \sigma' = \beta(f)(\sigma'_X, \sigma'_X) - (\lambda p/m) \sigma_X,$$

where $\nabla_{\sigma'_X} \sigma'_X = 0$ since $\gamma_X$ is a geodesic. Using this, we have

$$\sigma^{(3)}_X = D_{\sigma'_X} \sigma''_X = D_{\sigma'_X} \beta(f)(\sigma'_X, \sigma'_X) - (\lambda p/m) \sigma'_X)$$

$$= \nabla^\perp_{\sigma'_X} \beta(f)(\sigma'_X, \sigma'_X) - A(f)_{\beta(f)}(\sigma'_X, \sigma'_X) - (\lambda p/m) \sigma'_X,$$

where $\nabla^\perp$ denotes the covariant differentiation of the normal bundle $N_f$ of $f : S^m \to S_V$ and $A(f)$ is the shape operator of $f$. For unit tangent vectors $X,Y \in T_x(S^m)$, $x \in S^m$, this gives

$$\langle \sigma^{(3)}_X(0), \sigma'_Y(0) \rangle = -\langle A(f)_{\beta(f)}(X,X)X, Y \rangle - (\lambda p/m) \langle X, Y \rangle.$$

The equivalence of (3) and (20) is now clear.

Setting $X = Y \in T_x(S^m)$, $x \in S^m$, with $\|X\| = 1$, we obtain

$$\langle \sigma^{(3)}_X(0), \sigma'_X(0) \rangle = -\|\beta(f)(X,X)\|^2 - \frac{\lambda p}{m} = -\Lambda_2^2 - \frac{\lambda p}{m}.$$

The last statement in (4) and thereby Theorem A follows.
3.2 Proof of Theorem B

We first need to develop several computational tools.  
In the Lie algebra $su(2)$ we take the standard (orthonormal) basis:

$$X = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, \quad Y = \begin{bmatrix} 0 & i \\ i & 0 \end{bmatrix}, \quad Z = \begin{bmatrix} i & 0 \\ 0 & -i \end{bmatrix}.$$ 

The unit sphere $S_{su(2)} \subset su(2)$ can then be parametrized by spherical coordinates as

$$U = U(\theta, \varphi) = \cos \theta \cos \varphi \cdot X + \sin \theta \cos \varphi \cdot Y + \sin \varphi \cdot Z$$

$$= \begin{bmatrix} i \sin \varphi & e^{i \theta} \cos \varphi \\ -e^{-i \theta} \cos \varphi & -i \sin \varphi \end{bmatrix} \in S_{su(2)}, \quad \theta, \varphi \in \mathbb{R}.$$ 

(For simplicity, unless needed, we suppress the angular variables.) An important feature of the spherical coordinates to be used in the sequel is that, for given $\theta, \varphi \in \mathbb{R}$, the vectors $U(\theta, \varphi)$, $U(\theta + \pi/2, 0)$, and $U(\theta, \varphi + \pi/2)$ form an orthonormal basis of $su(2)$ (which, for $\theta = \varphi = 0$ reduces to the standard basis above).

Moreover, since $U^2 = -I$, we have

$$U^{2l} = (-1)^l I \quad \text{and} \quad U^{2l+1} = (-1)^l U, \quad l \geq 1.$$ 

Hence, for the exponential map $\exp : su(2) \to SU(2)$, we obtain

$$\exp(t \cdot U) = \sum_{j=0}^{\infty} \frac{1}{j!}(tU)^j = \sum_{l=0}^{\infty} (-1)^l \frac{t^{2l}}{(2l)!} U^{2l} + \sum_{l=0}^{\infty} (-1)^l \frac{t^{2l+1}}{(2l+1)!} U^{2l+1}$$

$$= \cos t \cdot I + \sin t \cdot U = \begin{bmatrix} \cos t + i \sin \varphi \sin t & e^{i \theta} \cos \varphi \sin t \\ -e^{-i \theta} \cos \varphi \sin t & \cos t - i \sin \varphi \sin t \end{bmatrix}, \quad t \in \mathbb{R}.$$ 

Recall from Section 1 the equivariant construction which associates to a unit vector $\xi \in W_p, \ p \geq 4$, the orbit map $f_\xi : S^3 \to S_{W_p}$ defined by

$$f_\xi(g) = g \cdot \xi = \xi \circ g^{-1}, \quad g \in SU(2).$$ 

Here $SU(2) = S^3$, the unit sphere in $\mathbb{C}^2$. For computational purposes it is convenient to identify $\mathbb{C}^2$ with the space of quaternions $\mathbb{H}$ via $(a, b) \mapsto a + jb, \ (a, b) \in \mathbb{C}^2$. With this, $S^3$ becomes the unit sphere $S_{\mathbb{H}}$. The unit quaternion $g = a + jb \in S_{\mathbb{H}}$ has the inverse

$$g^{-1} = g^* = (\bar{a}, -b) = (a + jb)^{-1} = \bar{a} - jb.$$ 

16
Using the realization \( W_p \) as an \( SU(2) \)-submodule of \( \mathbb{C}[z, w] \), we obtain the explicit representation

\[
\begin{align*}
  f_\xi(g)(z, w) &= \xi(g^{-1}(z, w)) = \xi((a - jb)(z + jw)) \\
  &= \xi((\bar{a}z + \bar{b}w + j(-bz + aw)) \\
  &= \xi(\bar{a}z + \bar{b}w, -bz + aw), \quad g = (a, b) = a + jb \in S^3.
\end{align*}
\]

For the proof of Theorem B we need to simplify the condition of isotropy of \( f_\xi \) in Theorem A. As the first step we note that, since \( f_\xi \) is \( SU(2) \)-equivariant, the vanishing of the scalar products in (3) need to hold only for unit vectors in the tangent space \( T_1(S^3) = su(2) \).

Let \( U \in T_1(S^3) = T_1(SU(2)) = su(2) \) be a unit vector, and consider the geodesic \( \gamma_U : \mathbb{R} \to S^3 \), \( \gamma_U(0) = 1 \) and \( \gamma_U(0) = U \). Letting \( U = U(\theta, \varphi) \), \( \theta, \varphi \in \mathbb{R} \), by (26), we have

\[
\gamma_U(t) = (\cos t + i \sin \varphi \sin t, -e^{-i\theta} \cos \varphi \sin t) \in S^3, \quad t \in \mathbb{R}.
\]

Following Theorem A, we let \( \sigma_U = f_\xi \circ \gamma_U : \mathbb{R} \to S_{W_p} \) be the image curve under \( f_\xi \).

By the explicit representation above, we obtain

\[
\sigma_U(t) = \xi(a(t), b(t)), \quad t \in \mathbb{R},
\]

where

\[
\begin{align*}
  a(t) &= a(t, \theta, \varphi) := (\cos t - i \sin \varphi \sin t)z - (e^{i\theta} \cos \varphi \sin t)w \\
  &= z \cdot \cos t + (-i \sin \varphi \cdot z - e^{i\theta} \cos \varphi \cdot w) \sin t, \\
  b(t) &= b(t, \theta, \varphi) := (e^{-i\theta} \cos \varphi \sin t)z + (\cos t + i \sin \varphi \sin t)w \\
  &= w \cdot \cos t + (e^{-i\theta} \cos \varphi \cdot z + i \sin \varphi \cdot w) \sin t.
\end{align*}
\]

It is a simple but crucial fact that, for given \( \theta, \varphi \in \mathbb{R} \), the pair \( (a(t), b(t)) \), \( t \in \mathbb{R} \), satisfies the system of differential equations

\[
\begin{align*}
  \frac{da}{dt} &= -i \sin \varphi \cdot a(t) - e^{i\theta} \cos \varphi \cdot b(t), \\
  \frac{db}{dt} &= e^{-i\theta} \cos \varphi \cdot a(t) + i \sin \varphi \cdot b(t),
\end{align*}
\]

with initial conditions \( a(0) = z, b(0) = w \). (Note that the coefficient matrix is in \( SU(2) \).)

We now expand \( \xi \in W_p \) as in (5). Evaluating \( \xi \) on the pair \( (a(t), b(t)) \), \( t \in \mathbb{R} \), by (27), we obtain

\[
\sigma_U(t) = \sum_{q=0}^p c_q a(t)^{p-q} b(t)^q, \quad t \in \mathbb{R}.
\]

17
(It will be convenient to define \( c_q = 0 \) for the out-of-range indices \( q < 0 \) and \( q > p \).)

Taking derivatives and using the system of differential equations above, a simple induction gives the following:

**Lemma 1** Given \( \theta, \phi \in \mathbb{R} \), for any \( k \in \mathbb{N} \), we have

\[
\sigma_{U_1}^{(k)}(t) = \sum_{q=0}^{p} c_q^{(k)}(\theta, \phi) a(t)^{p-q} b(t)^q, \quad t \in \mathbb{R},
\]

where the coefficients \( c_q^{(k)} = c_q^{(k)}(\theta, \phi) \) are given by

\[
c_q^{(k)} = e^{-i\theta} \cos \phi \cdot (q+1)c_{q+1}^{(k-1)} - i \sin \phi \cdot (p-2q)c_q^{(k-1)} \\
- e^{i\theta} \cos \phi \cdot (p-q+1)c_{q-1}^{(k-1)}, \quad q = 0, \ldots, p.
\]

(28)

Here \( c_q^{(0)} = c_q \), \( q \in \mathbb{Z} \), and \( c_q^{(k)} = 0 \) for the out-of-range indices \( q < 0 \) and \( q > p \).

We now assume that \( f_\xi : S^3 \rightarrow S_{W_p} \) is a spherical minimal immersion, that is, the coefficients of \( \xi \) in the expansion (5) satisfy (6)-(9). Our task is to give a necessary and sufficient condition for \( f_\xi \) to be isotropic (of order two).

We now let

\[
U_1 := U(\theta, \phi), \quad U_2 := U(\theta + \pi/2, 0), \quad U_3 := U(\theta, \phi + \pi/2), \quad \theta, \phi \in \mathbb{R}.
\]

We observe that, for given \( \theta, \phi \in \mathbb{R} \), \( \{U_1, U_2, U_3\} \subset T_1(S^3) \) is an orthonormal basis. Due to the arbitrary position of \( U_1 \) (given by the arbitrary choices of \( \theta \) and \( \phi \)), and linearity in the first derivative in (3), Theorem A gives the following:

**Lemma 2** Let \( f_\xi : S^3 \rightarrow S_{W_p} \) be an \( SU(2) \)-equivariant spherical immersion. Then \( f_\xi \) is isotropic if and only if, for any \( \theta, \phi \in \mathbb{R} \), we have

\[
\langle \sigma_{U_1}^{(3)}(0), \sigma_{U_2}'(0) \rangle = \langle \sigma_{U_1}^{(3)}(0), \sigma_{U_3}'(0) \rangle = 0.
\]

(29)

In this case, for the constant of isotropy \( \Lambda_2 \), we have \( \langle \sigma_{U_1}^{(3)}(0), \sigma_{U_1}'(0) \rangle = -\Lambda_1^2 - \Lambda_2^2 \).

For the proof of Theorem B we need a convenient scalar product on \( W_p \subset \mathbb{C}[z, w] \), or, more generally, on the space of complex spherical harmonics \( H_p^3 \). As usual, we identify \( H_p^3 \) with the space of complex-valued degree \( p \) harmonic homogeneous polynomials on \( \mathbb{C}^2 = \mathbb{R}^4 \). To define this scalar product, we will regard a complex polynomial \( \chi \) in the complex variables \( z, w \in \mathbb{C} \) as a real polynomial in the variables \( z, w, \bar{z}, \bar{w} \). Then, for \( \chi_1, \chi_2 \in H_p^3 \), we define the scalar product on \( H_p^3 \) by

\[
\langle \chi_1, \chi_2 \rangle = \Re \left( \chi_1 \left( \frac{\partial}{\partial \bar{z}} \frac{\partial}{\partial \bar{w}} - \frac{\partial}{\partial z} \frac{\partial}{\partial w} \right) \chi_2 \right),
\]

18
where $\Re$ stands for real part, and $\chi_1$ acts on the conjugate $\overline{\chi_2}$ as a polynomial differential operator. (This form of the scalar product on $H^3_p$ has been used in [5, 6, 27].) Note that, with respect to this scalar product, $\left\{ z^{p-q} w^q / \sqrt{(p-q)!q!} \right\}_{q=0}^p$ is an orthonormal basis of $W_p$ as stated in Section 1.

**Proof of Theorem B.** We need to work out the two scalar products in (29) in terms of the coefficients $c_q$, $q = 0, \ldots, p$, in (5). In both cases the explicit calculations are very similar. The vanishing of the first scalar product will imply (10)-(13), while the vanishing of the second will give (10)-(14). Hence we will treat only the second scalar product in (29).

Using Lemma 1, for fixed $\theta, \varphi \in \mathbb{R}$, we have

$$\langle \sigma^{(3)}_{U_1}(0), \sigma^{(4)}_{U_3}(0) \rangle = \Re \left( \sum_{q=0}^{p} (p-q)!q! \cdot \overline{c_q^{(3)}(\theta, \varphi)} c_q^{(1)}(\theta, \varphi + \pi/2) \right) = \sum_{k=-4}^{4} e^{k\theta B_k}, \ (30)$$

where the last exponential sum is obtained by repeated application of the recurrence in (28). In this last sum each $B_k$, $k = -4, \ldots, 4$, is independent of the variable $\theta$. In particular, the scalar product on the left-hand side of (30) vanishes for all $\theta, \varphi \in \mathbb{R}$ if and only if the (Fourier) coefficients $B_k$, $k = -4, \ldots, 4$, vanish for all $\varphi \in \mathbb{R}$.

Expanding the factors $c_q^{(3)}(\theta, \varphi) c_q^{(1)}(\theta, \varphi + \pi/2)$, $q = 0, \ldots, p$, in (30) in terms of the coefficients $c_q$, $q = 0, \ldots, p$, requires long but straightforward computations. It turns out that the expressions

$$e^{k\theta B_k} + e^{-k\theta B_{-k}}, \quad k = 0, \ldots, 4, \quad (31)$$

are the least cumbersome to determine. (For $k = 0$, this reduces to $2B_0$ which we included here.)

We begin with the simplest case, namely $k = 4$. As noted above, a straightforward computation gives

$$e^{4\theta B_4} + e^{-4\theta B_{-4}} = 2 \cos^3 \varphi \sin \varphi \sum_{q=0}^{p-4} (p-q)!(q+4)! \cdot \Re \left( e^{4\theta c_q \overline{c_{q+4}}} \right).$$

Clearly, this vanishes for all $\theta, \varphi \in \mathbb{R}$ if and only if (10) holds.

The cases $k = 1, 2, 3$ are similar but longer. We will discuss only the case $k = 1$. 19
We have

\[ e^{i\theta} B_1 + e^{-i\theta} B_{-1} = \frac{\cos^4 \varphi}{2} \sum_{q=0}^{p-1} (p-q)!(q+1)! \]

\[ - \frac{3 \cos^2 \varphi \sin^2 \varphi}{2} \sum_{q=0}^{p-1} (p-q)!(q+1)! \]

\[ \cdot \left[ (p-2q-1)^3 + 2(4-(p+1)^2)(p-2q-1) \right] \cdot \Im \left( e^{i\theta} c_q \bar{c}_{q+1} \right) \]

\[ - \left( 15(p-2q)^4 + 18(2-p(p+2))(p-2q)^2 + 3p^2(p+2)^2 - 8p(p+2) \right) |c_q|^2 \]

\[ + \frac{\cos \varphi \sin^3 \varphi}{2} \sum_{q=0}^{p} (p-q)!q! \]

\[ \cdot \left[ 5(p-2q)^4 - (3p(p+2) - 16)(p-2q)^2 - 4p(p+2) \right] |c_q|^2. \]

(32)

where \( \Im \) stands for imaginary part. Due to (8), the second term (with common factor \((p-2q-1)\)) in each square bracket cancels. With this the simplified expression vanishes for all \( \theta, \varphi \in \mathbb{R} \) if and only if (13) holds. (Note that we recover (13) three times corresponding to each sum above.)

The cases \( k = 3 \) and \( k = 2 \) are similar and they yield (11) and (12), respectively. Finally, we treat the case \( k = 0 \). We have

\[ B_0 = \frac{\cos^3 \varphi \sin \varphi}{8} \sum_{q=0}^{p} (p-q)!q! \]

\[ \cdot \left[ 15(p-2q)^4 + 18(2-p(p+2))(p-2q)^2 + 3p^2(p+2)^2 - 8p(p+2) \right] |c_q|^2 \]

\[ - \frac{\cos \varphi \sin^3 \varphi}{2} \sum_{q=0}^{p} (p-q)!q! \]

\[ \cdot \left[ 5(p-2q)^4 - (3p(p+2) - 16)(p-2q)^2 - 4p(p+2) \right] |c_q|^2. \]

(We keep the factor \( p(p+2) \) intact as it is the \( p \)th eigenvalue of the Laplacian on \( S^3 \).) Now, \( B_0 = 0 \) for all \( \theta, \varphi \in \mathbb{R} \) if and only if each of the two sums above vanish separately. We split the first as

\[ 15 \sum_{q=0}^{p} (p-q)!q!|c_q|^2 + 18(2-p(p+2)) \sum_{q=0}^{p} (p-q)!q!(p-2q)^2|c_q|^2 \]

\[ + (3p^2(p+2)^2 - 8p(p+2)) \sum_{q=0}^{p} (p-q)!q!|c_q|^2 = 0. \]

20
By (9) and (6), the second and third sums are equal to \( p(p+2)/3 \) and 1, respectively. Rearranging, we obtain (14). The second sum in (32) gives the same result.

Finally, to determine the constant of isotropy \( \Lambda_2 \), in view of (4) in the last statement of Theorem A, we need to calculate

\[
\langle \sigma^{(3)}_{U_1}(0), \sigma'_{U_1}(0) \rangle = R \left( \sum_{q=0}^{p} (p-q)!q! \cdot c_q^{(3)}(\theta, \varphi) \overline{c_q^{(1)}(\theta, \varphi)} \right).
\]

Once again expanding, akin to the previous computations, we obtain

\[
\langle \sigma^{(3)}_{U_1}(0), \sigma'_{U_1}(0) \rangle = \frac{-p(p+2)(3p(p+2) - 4)}{15}.
\]

Combining this with (4), the last statement of Theorem B follows.

Acknowledgment The authors wish to thank the referee for the careful reading and the many suggestions which led to the improvement of the original manuscript.
